Executive summary

Australia's rental market has faced mounting affordability pressures in recent years, driven by population growth, constrained housing supply, and shifting demand patterns in the post-pandemic period. In 2026, these pressures continue to manifest unevenly across states and dwelling types, making it critical to understand where and how rental costs are concentrated. This report presents a structured analysis of residential rental listings across Australia, with a focus on uncovering geographic and dwelling-type disparities in weekly rental prices.

The analysis draws on the **Australian Rental Market Data 2026** dataset sourced from Kaggle [1], comprising 6,766 cleaned observations across 9 variables. The dataset captures weekly rental prices alongside key dwelling characteristics such as property type, number of bedrooms, bathrooms, and parking spaces, as well as geographic identifiers including state, suburb, and locality. After removing one duplicate record, the dataset provided a reliable national snapshot of the rental landscape.

Key findings reveal that rental prices vary substantially across both dwelling type and location. Acreage and semi-rural properties command the highest median weekly rent at AUD 970, while

studios remain the most affordable category at AUD 430. Geographically, Queensland recorded the highest rental stress rate at 75.1%, while the ACT recorded the lowest at 11.7%, highlighting that income levels are just as important as rent prices in determining affordability. These findings underscore the growing divide in housing affordability across Australian regions and dwelling categories, with important implications for renters, policymakers, and housing stakeholders.

Introduction

Australia’s housing market has been the subject of considerable public and policy debate in recent years. Rental affordability, in particular, has deteriorated across major cities and regional centres alike, as demand continues to outpace supply. Factors such as net overseas migration, low vacancy rates, and rising construction costs have placed sustained upward pressure on weekly rents, making it increasingly difficult for low- to middle-income households to secure stable housing. Against this backdrop, a data-driven examination of current rental conditions is both timely and necessary.

This report investigates rental price variation and affordability stress across Australia using the **Australian Rental Market Data 2026** dataset obtained from Kaggle [1]. The dataset provides a comprehensive national snapshot of residential rental listings in 2026, encompassing properties across all Australian states and territories. It includes variables pertaining to weekly rental price, dwelling type, property characteristics such as bedroom and bathroom count, and geographic attributes at the suburb and state level. This combination of price, property, and location data makes it well suited to exploring the structural and geographic dimensions of rental affordability.

The primary aim of this analysis is to examine how weekly rental prices and rental stress differ across dwelling types and Australian states, and to identify patterns that reflect broader dynamics in the national housing market. Rental stress is assessed using the standard 30% income-to-rent benchmark [2], applied relative to each state’s median weekly household income. The report is structured as follows — the Methodology section outlines the dataset and cleaning procedures; the Results section presents key visualisations and findings; and the Discussion, Conclusion and Recommendations section interprets results and offers evidence-based policy directions.

Methodology

Before analysis, the dataset was reviewed for missing values, duplicate observations, and variable suitability. One duplicated observation was identified and removed. Missing values occurred only in variables outside the scope of this study and were therefore not treated. Variables unrelated to the research objective, including listing text and detailed address information, were excluded from the analysis. Rental stress was assessed using the standard housing affordability benchmark, where a property was classified as being in rental stress if weekly rent exceeded 30% of the median weekly household income for the corresponding state [2].

Dataset Description

The cleaned dataset contains 6766 observations and 9 variables. The retained variables include numeric measures describing rental price and dwelling characteristics (`price_display`, `bedrooms`, `bathrooms`, and `parking_spaces`) and categorical variables describing location and dwelling

category (`state`, `locality`, `suburb`, and `propertyType`). These variables provide the basis for examining rental stress across Australian regions and dwelling types in 2026.

Dataset Summary

Table 1 summarises the distribution of dwelling types represented in the Australian rental dataset for 2026. Houses accounted for the largest share of observations (4,089 properties; 60.4%), followed by apartments (1,369 properties; 20.2%) and units (761 properties; 11.2%). Together, these dwelling types comprised over 90% of all rental listings, indicating that the dataset primarily reflects conventional residential dwellings.

Table 1: Distribution of rental properties by dwelling type

Property type	Number of properties	Percentage (%)
house	4089	60.4
apartment	1369	20.2
unit	761	11.2
townhouse	142	2.1
duplex/semi-detached	134	2.0
studio	104	1.5
flat	85	1.3
other	33	0.5
villa	25	0.4
acreage/semi-rural	17	0.3
terrace	7	0.1

In addition to dwelling type composition, Figure 1 shows the distribution of rental properties across Australia in 2026. Most observations were from New South Wales, followed by Victoria and Western Australia, indicating broad geographic coverage of the Australian rental market.

The cleaned dataset and descriptive summaries provide the foundation for evaluating rental stress across Australian regions and dwelling types in 2026.

Figure 1: Distribution of rental properties across Australian states

Results

Rental stress is defined here as weekly rent exceeding 30% of the median weekly household income for each state, following the standard affordability benchmark [2]. Across the full dataset, 59.5% of listings meet this threshold, indicating that the majority of available rentals in 2026 are unaffordable for a median-income household.

Figure 2 shows the proportion of listings classified as rental stress by state. Queensland recorded the highest stress rate (75.1%), followed by Western Australia (71.6%) and Tasmania (67.3%). Despite having the highest median weekly rent, the Australian Capital Territory had the lowest stress rate (11.7%), reflecting its substantially higher median household income relative to other states. New South Wales, while recording a moderate stress rate of 62.2%, had the largest absolute number of stressed listings (1,678 properties) due to its volume of listings.

Figure 2: Proportion of rental listings exceeding the 30% income threshold (rental stress) by Australian state, 2026.

Rental stress by dwelling type

Table 2 summarises the rental stress rate and median weekly rent for each dwelling type. Acreage and semi-rural properties recorded the highest stress rate (88.2%) and the highest median rent (\$970/wk), making them the least affordable dwelling category. Houses (65.2%) and apartments (63.1%) followed, representing the most common dwelling types in the dataset. Studios recorded the lowest stress rate (11.5%) and the lowest median rent (\$430/wk), making them the most accessible option for renters on median incomes.

Table 2: Rental stress rate and median weekly rent by dwelling type.

Property type	Number of listings	Median rent (\$/wk)	Stress rate (%)
acreage/semi-rural	17	970	88.2
terrace	7	750	71.4
townhouse	142	700	65.5
house	4089	695	65.2
apartment	1369	700	63.1
duplex/semi-detached	134	650	51.5
villa	25	590	44.0
unit	761	550	36.5
other	33	540	21.2
flat	85	510	11.8
studio	104	430	11.5

Discussion

The findings reveal a rental market under considerable strain. With nearly 60% of all listings exceeding the 30% affordability threshold, rental stress reflects a structural mismatch between housing costs and household incomes across most of Australia. Queensland’s stress rate of 75.1% is particularly striking, surpassing even New South Wales despite NSW carrying the largest absolute number of unaffordable listings (1,678 properties). This divergence suggests that stress rates and raw listing volumes tell different stories — Queensland renters face a more acute affordability problem proportionally, while NSW presents the greatest overall scale of housing pressure [2].

The ACT stands out as a clear outlier. Despite recording the highest median rent among all states, its stress rate of just 11.7% demonstrates that rent levels alone do not determine affordability — household income plays an equally decisive role. Because the 30% threshold is applied relative to each state’s median weekly income, the ACT’s substantially higher income base shields most renters from stress classification, even at elevated rent levels. This reinforces the importance of income-adjusted affordability measures over simple rent comparisons [2].

At the dwelling level, the results reveal a clear affordability gradient. Acreage and semi-rural properties recorded the highest stress rate (88.2%) and the highest median rent (\$970/week), making them the least accessible category for median-income renters. Houses (65.2%) and apartments (63.1%) also recorded high stress rates, indicating that affordability pressure is concentrated in the most common dwelling types. Studios recorded the lowest stress rate (11.5%) and the lowest median rent (\$430/week), making them the most accessible option in the dataset. As this study is limited to listed rental properties, conclusions about broader supply availability cannot be drawn from these figures alone.

Conclusion

This study examined rental affordability across Australia in 2026 using a dataset of residential listings, applying the standard 30% income-to-rent benchmark to assess rental stress at both the state and dwelling-type level [2].

The results paint a sobering picture. Nearly three in five rental listings nationally exceed the affordability threshold, confirming that rental stress is the norm rather than the exception in the current Australian market. At the state level, Queensland, Western Australia, and Tasmania emerged as the most financially pressured regions — not necessarily because their rents are the highest, but because their household incomes are comparatively lower, making even moderate rents unaffordable for median-earning households [3]. The ACT's low stress rate (11.7%) despite its high median rent reinforces this point clearly: income is the more powerful determinant of affordability than rent price alone.

At the dwelling level, the findings reveal a clear affordability gradient. Acreage and semi-rural properties are the least accessible, with an 88.2% stress rate and a median rent of \$970 per week — placing them well beyond reach for most renters. Conventional dwellings such as houses and apartments, which make up the bulk of the market, also recorded high stress rates (65.2% and 63.1% respectively), suggesting that even mainstream housing options are increasingly unaffordable. Studios stand out as the most accessible dwelling type, with a stress rate of just 11.5% and a median rent of \$430 per week, though their small share of total listings limits their impact as a broad solution.

Taken together, these findings indicate that rental unaffordability in Australia in 2026 is both widespread and structurally entrenched, varying meaningfully by both geography and dwelling type.

Recommendations

Based on these findings, several policy directions warrant consideration.

First, state governments in Queensland, Western Australia, and Tasmania should be prioritised for targeted rental relief measures. Given that stress in these states is driven largely by the income-rent gap rather than extreme rent levels alone, income-side interventions — such as expanded Commonwealth Rent Assistance payments calibrated to state-level median incomes — are likely to be more effective than rent caps applied uniformly at the national level [4].

Second, increasing the supply of smaller, more affordable dwelling types — particularly studios and one-bedroom apartments — should be a planning priority in high-stress states. The data clearly show studios offer the most accessible entry point into the rental market, yet they represent a small fraction of total listings. Rezoning and density incentives in well-connected urban areas could help grow this segment of supply [5].

Third, the affordability crisis in conventional housing categories (houses and apartments) demands attention given their dominance in the dataset. Policy levers such as build-to-rent schemes, social housing investment, and inclusionary zoning requirements for new developments could help moderate stress rates in these high-volume categories over the medium term [4].

Finally, this study highlights the limitations of applying a single national income benchmark to assess rental stress. Future research should incorporate suburb-level or postcode-level income data — available through the ABS — to produce more granular affordability assessments [3]. Integrating vacancy rates, rental growth trends, and household composition data would further strengthen the analytical basis for evidence-based housing policy in Australia.
